Elements and Operations

☞ A **symmetry element** is an imaginary geometrical construct about which a symmetry operation is performed.

☞ A **symmetry operation** is a movement of an object about a symmetry element such that the object's orientation and position before and after the operation are indistinguishable.

✓ A symmetry operation carries every point in the object into an **equivalent** point or the **identical** point.

Point Group Symmetry

- All symmetry elements of a molecule pass through a central point within the molecule.

- The more symmetry operations a molecule has, the higher its symmetry is.

- Regardless of how many or few symmetry operations a molecule possesses, all are examples of one of five types.

Operation	Element	Element Construct
Identity, E	The object	N/A
Proper rotation, C_n	Proper axis, Rotation axis	line
Reflection, σ	Mirror plane, Reflection plane	plane
Inversion, i	Inversion center, Center of symmetry	point
Rotation-reflection Improper rotation, S_n	Improper axis, alternating axis	line

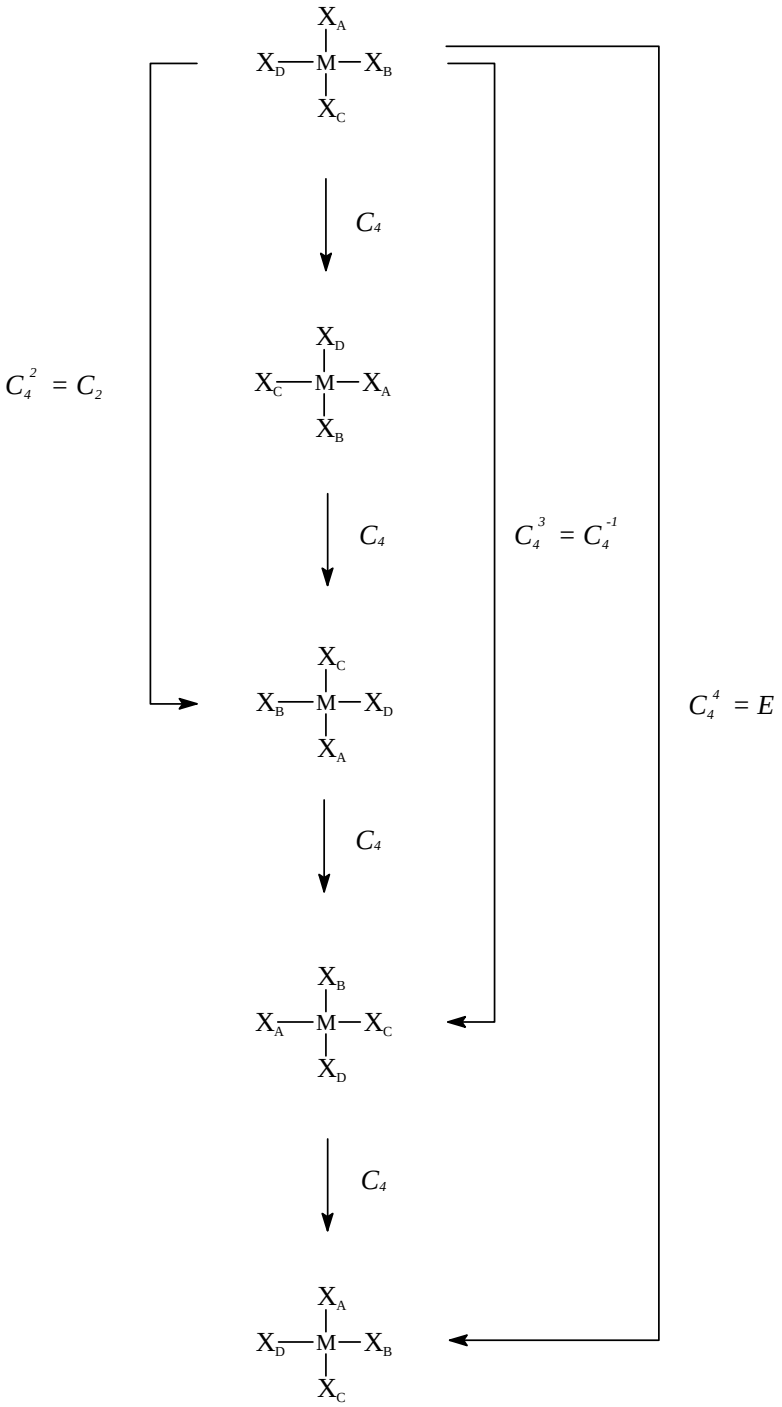
Proper Rotation, C_n

☞ If a molecule has rotational symmetry, rotation by $2\pi/n$ = $360°/n$ brings the object into an equivalent position.

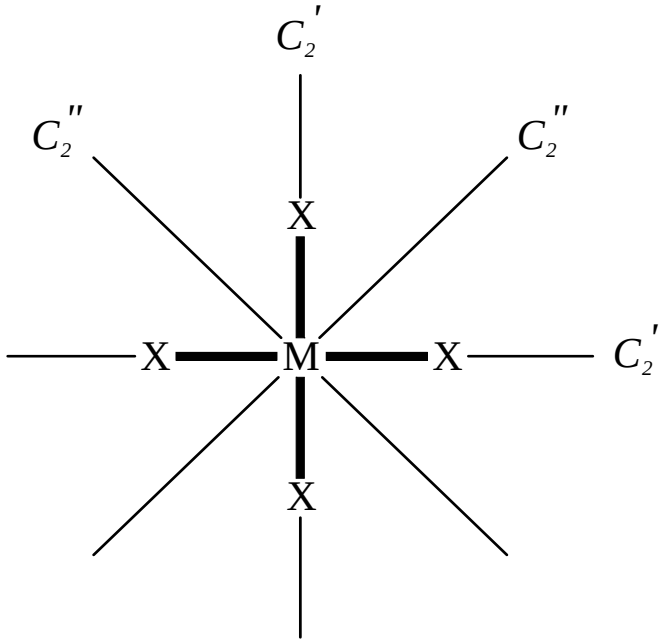
✓ The value of n is the **order** of an n-fold rotation.

✓ If the molecule has one or more rotational axes, the one with the highest value of n is the **principal axis of rotation**.

Successive C_4 clockwise rotations of a planar MX_4 molecule about an axis perpendicular to the plane of the molecule ($X_A = X_B = X_C = X_D$).



The C_2' and C_2'' axes of a planar MX_4 molecule.



General Relationships for C_n

$$C_n^{\,n} = E$$

$$C_n^{\,n/2} = C_2 \quad (n \text{ even})$$

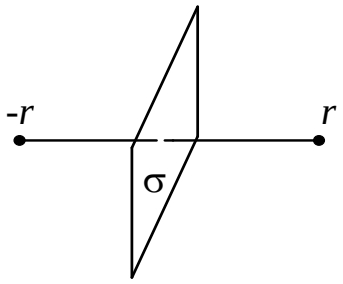
$$C_n^{\,n-1} = C_n^{\,-1}$$

$$C_n^{\,n+m} = C_n^{\,m} \quad (m < n)$$

✓ Every n-fold rotational axis has n–1 associated operations (excluding $C_n^{\,n} = E$).

Reflection, σ

☞ For every point a distance *r* along a normal to a mirror plane there exists a point at –*r*.



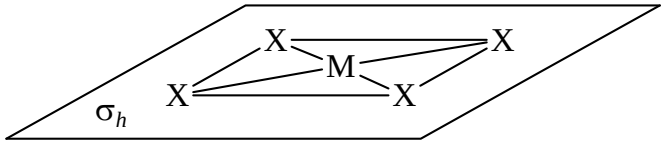
Two points, equidistant from a mirror plane σ, related by reflection

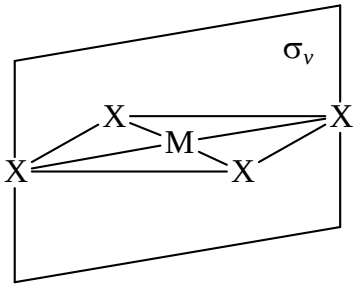
✓ For a point (*x*,*y*,*z*), reflection across a mirror plane σ_{xy} takes the point into (*x*,*y*,–*z*).

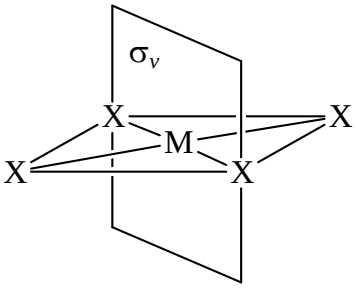
✓ Each mirror plane has only one operation associated with it, since $\sigma^2 = E$.

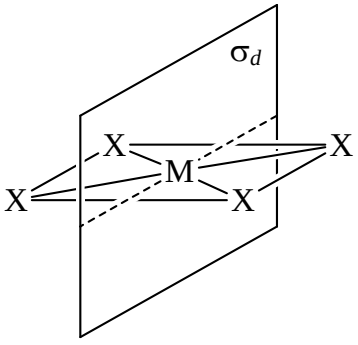
Horizontal, Vertical, and Dihedral Mirror Planes

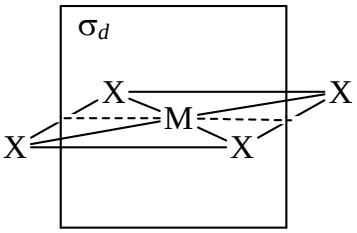
Mirror planes of a square planar molecule MX_4.







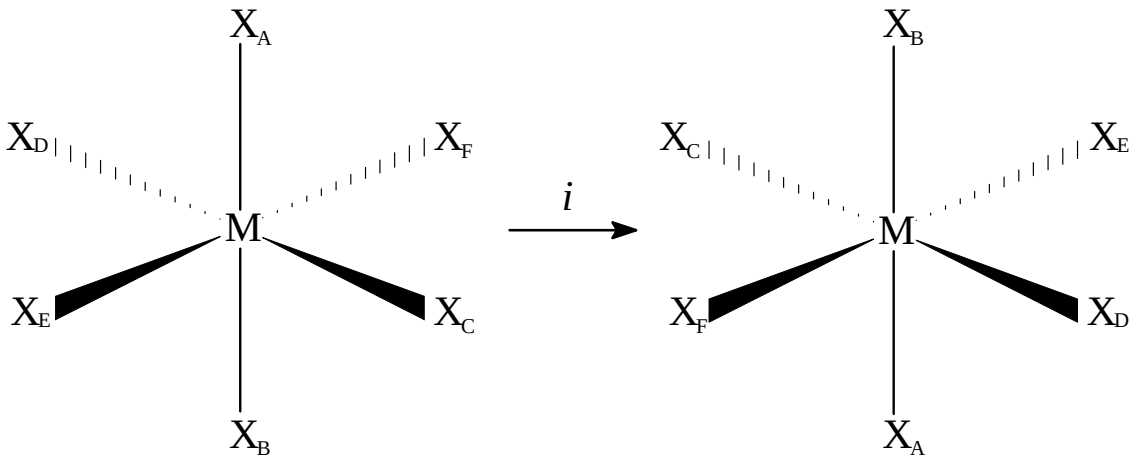




Inversion, *i*

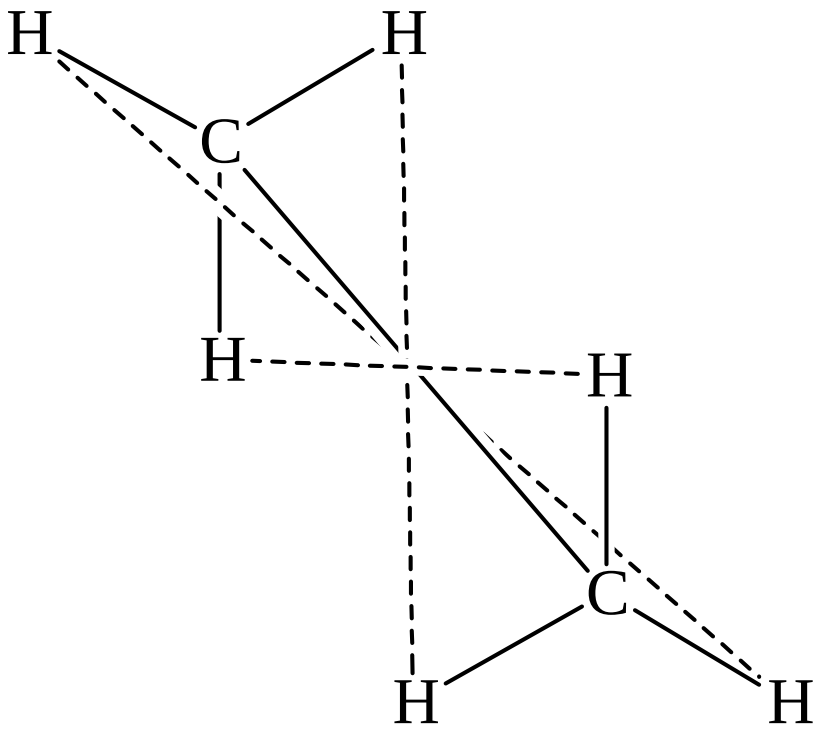
☞ If inversion symmetry exists, for every point (x,y,z) there is an equivalent point $(-x,-y,-z)$.

✓ Each inversion center has only one operation associated with it, since $i^2 = E$.



Effect of inversion (i) on an octahedral MX_6 molecule ($X_A = X_B = X_C = X_D = X_E = X_F$).

Inversion Center of Ethane in Staggered Configuration



Ethane in the staggered configuration. The inversion center is at the midpoint along the C-C bond. Hydrogen atoms related by inversion are connected by dotted lines, which intersect at the inversion center. The two carbon atoms are also related by inversion.

Rotation-Reflection (Improper Rotation), S_n

☞ S_n exists if the movements C_n followed by σ_h (or vice versa) bring the object to an equivalent position.

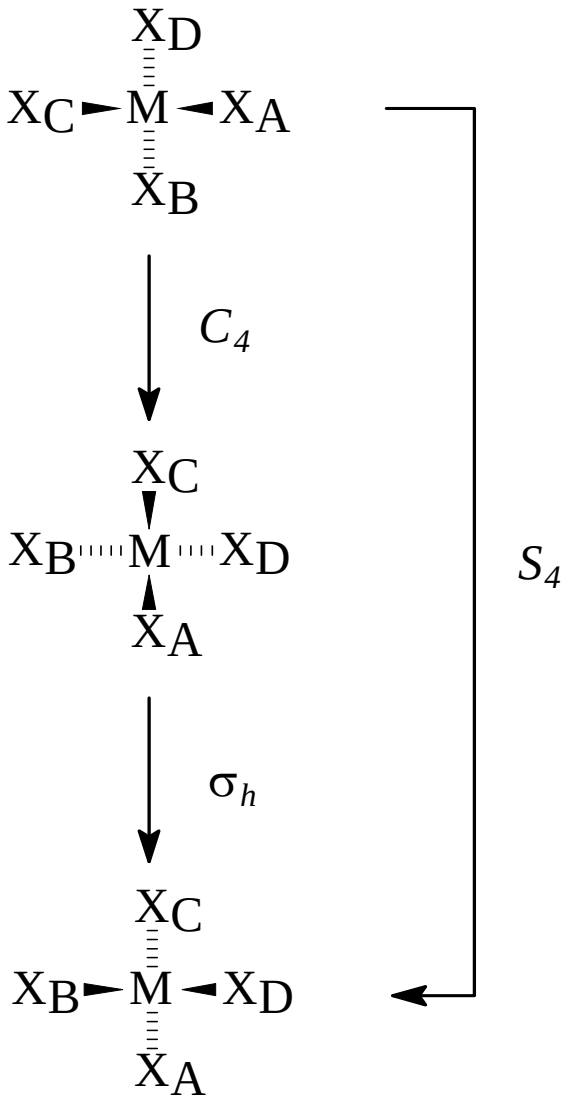
✓ If both C_n and σ_h exist, then S_n must exist.

Example: S_4 collinear with C_4 in planar MX_4.

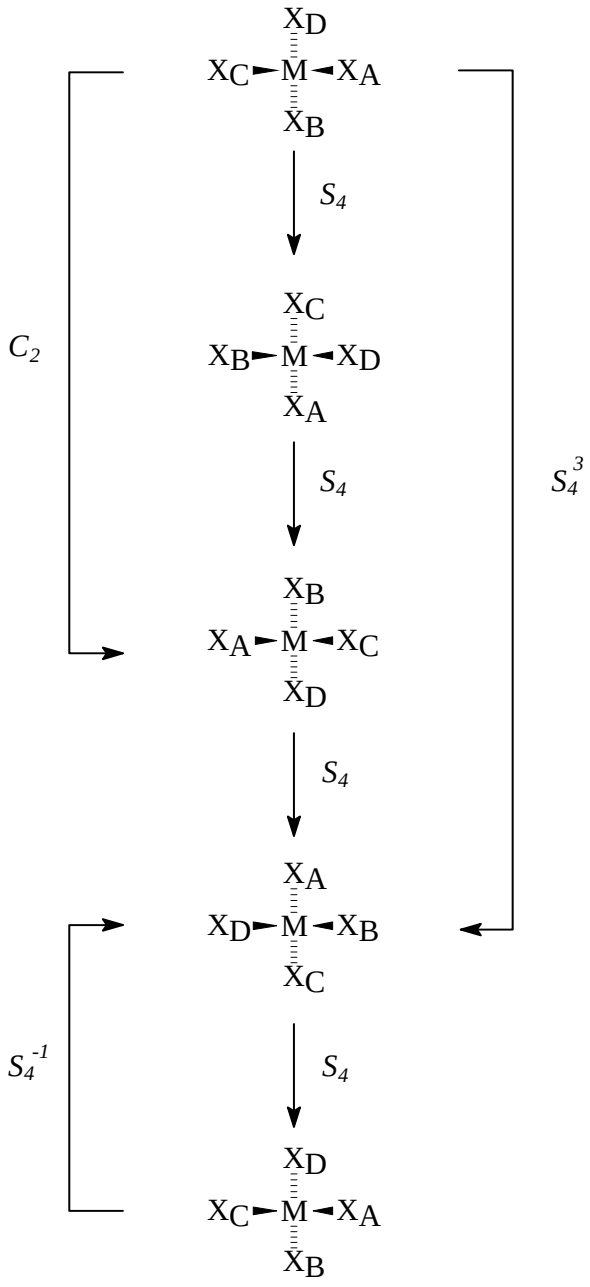
✓ Neither C_n nor σ_h need exist for S_n to exist.

Example: S_4 collinear with C_2 in tetrahedral MX_4.

S_4 Rotation of Tetrahedral MX_4

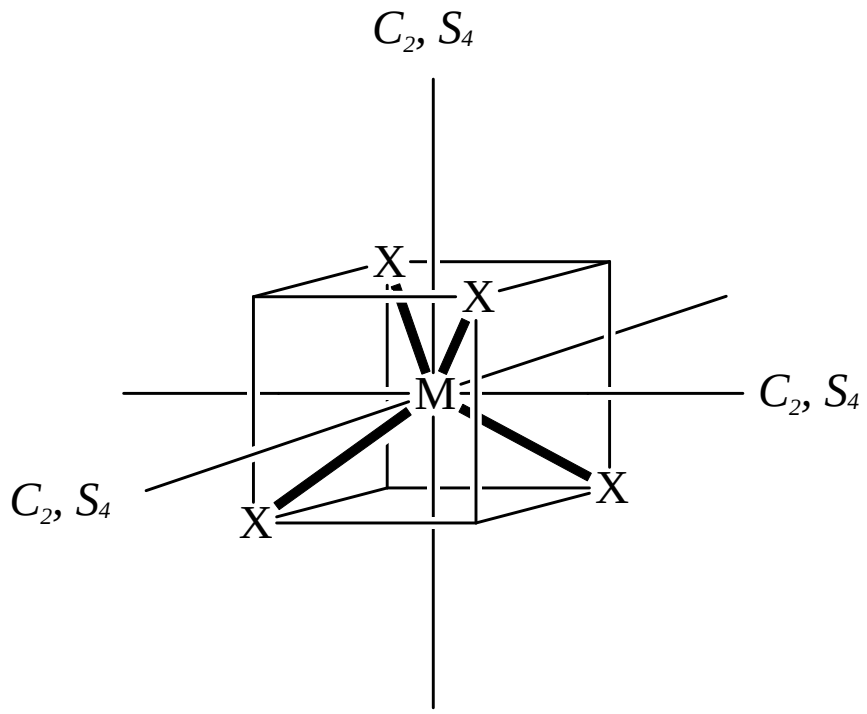


S_4 improper rotation of a tetrahedral MX_4 molecule ($X_A = X_B = X_C = X_D$). The improper axis is perpendicular to the page. Rotation is arbitrarily taken in a clockwise direction. Note that neither C_4 nor σ_h are genuine symmetry operations of tetrahedral MX_4.



Successive S_4 operations on a tetrahedral MX_4 molecule ($X_A = X_B = X_C = X_D$). Rotations are clockwise, except S_4^{-1}, which is equivalent to the clockwise operation S_4^3.

Representing a Tetrahedral MX_4 Molecule in a Cube

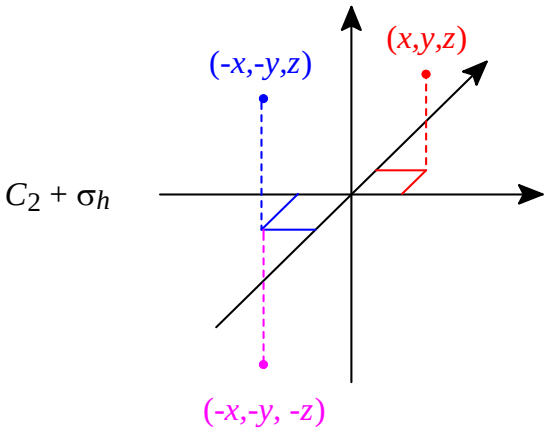


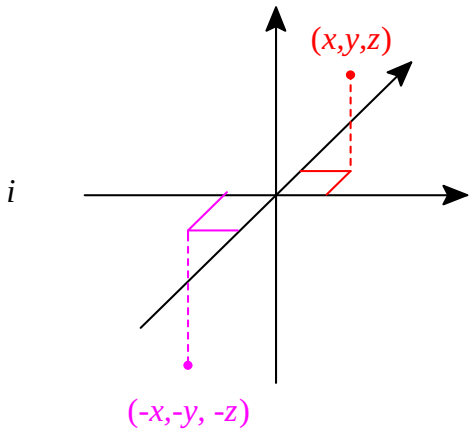
A C_2 axis, collinear with an S_4 axis, passes through the centers of each pair of opposite cube faces and through the center of the molecule.

Non-Genuine S_n Operations:

☞ $S_1 = \sigma$

☞ $S_2 = i$





General Relations of Improper Axes

Equivalences of successive S_n *operations:*

- ✓ If n is even, $S_n^{\,n} = E$
- ✓ If n is odd, $S_n^{\,n} = \sigma$ and $S_n^{\,2n} = E$
- ✓ If m is even, $S_n^{\,m} = C_n^{\,m}$ when $m < n$ and $S_n^{\,m} = C_n^{\,m-n}$ when $m > n$
- ✓ If S_n with even n exists, then $C_{n/2}$ exists
- ✓ If S_n with odd n exists, then both C_n and σ perpendicular to C_n exist.

Examples

☞ Find all symmetry elements and operations in the following:
