# $\pi$ bonding in an $O_h$ system

- The ligand field p orbitals are taken as a single set of 12 orbitals in an  $O_h$  environment as each set can be converted into every other axis by a symmetry operation, i.e. they are all mutually equivalent.

$$\Gamma_{\pi} = T_{1g} + T_{2g} + T_{1u} + T_{2u}$$

The axes for the ligand can be chosen in any consistent way. Here the x and y axes are orthogonal which is appropriate for p symmetry. Opposite ligands are also orthogonal to maintain  $O_h$  symmetry

$O_h$	$E$	$8C_3$	$6C_2$	$6C_4$	$3C_2(= C_4^2)$	$i$	$6S_4$	$8S_6$	$3\sigma_h$	$6\sigma_d$	
$\Gamma_{\pi}$	12	0	0	0	-4	0	0	0	0	0	
$T_{1g}$	3	0	-1	1	-1	3	1	0	-1	-1	$(d_{xy}, d_{xz}, d_{yz})$ $(p_x, p_y, p_z)$
$T_{2g}$	3	0	1	-1	-1	3	-1	0	-1	1	
$T_{1u}$	3	0	-1	1	-1	-3	-1	0	1	1	
$T_{2u}$	3	0	1	-1	-1	-3	1	0	1	-1	

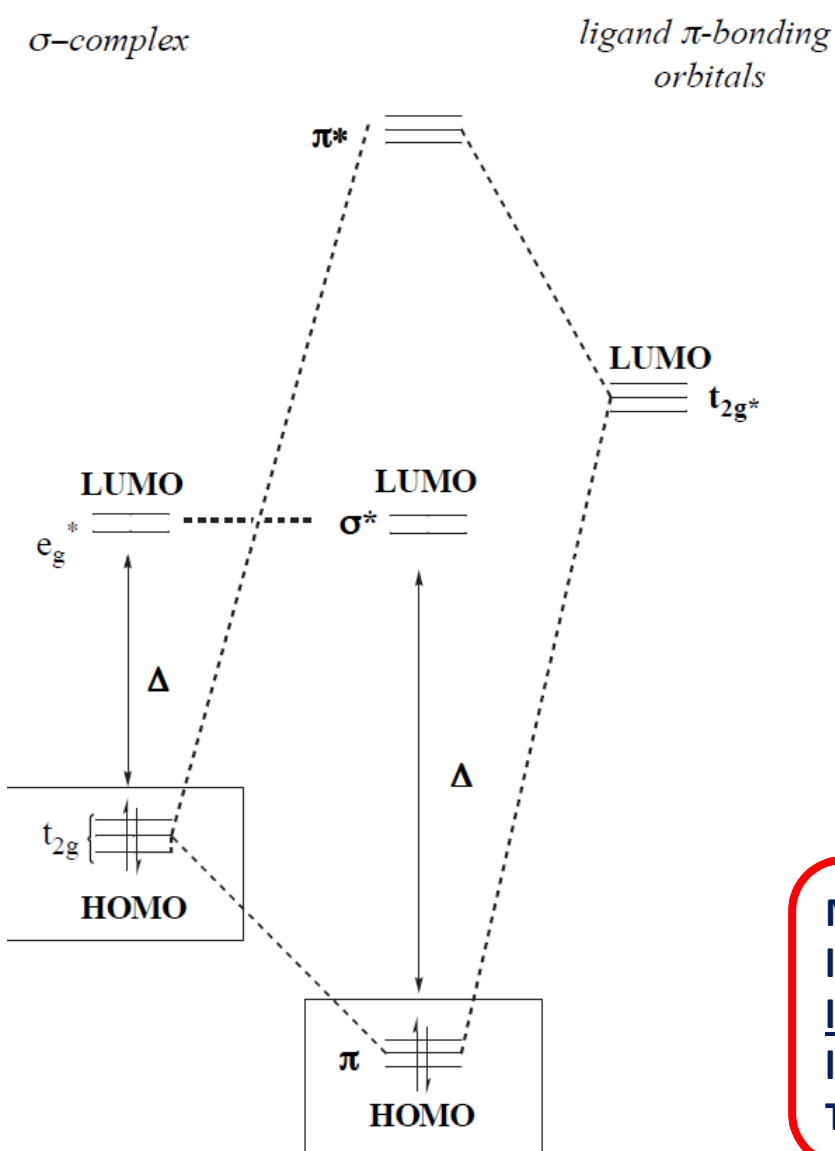

reducible representations of  $O_h$   $\pi$  orbitals

- Of these four representations, the  $T_{1g}$  and  $T_{2u}$  have no match among the metal orbitals.
- However, the  $T_{2g}$  representation matches the  $d_{xy}$ ,  $d_{xz}$ ,  $d_{yz}$  orbitals, and  $T_{1u}$  matches the  $p_x$ ,  $p_y$ ,  $p_z$  orbitals of the metal.
- The  $p$  orbitals of the metal have more favorable  $\sigma$  bonding interactions with the ligands and will not overlap well with the ligand  $p$  orbitals.
- The metal  $t_{2g}$  orbitals, which are non-bonding in the  $\sigma$  only  $O_h$  bonding picture now participate in  $\pi$  bonding with the  $T_{2g}$  ligand orbital distributed over the 6 ligands producing a  $t_{2g}$  bonding and corresponding anti-bonding set.
- $\pi$  bonding with transition metal complexes can occur with either filled or empty  $p$  or  $\pi^*$  ligand orbitals labeled  $\pi$ -donor and  $\pi$ -acceptor ligands respectively.

## MO description for M→L $\pi$ -acceptor system in an $O_h$ complex

- In the M→L  $\pi$ -acceptor system empty  $\pi^*$  ligand orbitals exist slightly higher in energy than the metal  $t_{2g}$  set with which overlap occurs.
- As a result MO's are formed with the bonding orbitals lower in energy than the initial metal  $t_{2g}$  set and the anti-bonding orbitals higher in energy than the  $e_g^*$   $\sigma$  anti-bonding orbitals.
- This stabilization of the  $t_{2g}$  orbitals through  $\pi$ -bonding increases the LFSE  $\Delta_o$  and increases the bond strength of the M-L bond through an increased bond order.
- This metal to ligand  $\pi$ -donation also known as  $\pi$ -backbonding makes the metal less basic thus stabilizing electron rich, low oxidation state metals, e.g.  $Cr(CO)_6$
- M→L  $\pi$ -backbonding represents a unique synergistic bonding situation where the greater the sigma donation to the metal, the greater the  $\pi$ -backbonding to the ligand.

# MO description for $M \rightarrow L$ $\pi$ -acceptor system in an $O_h$ complex

*“synergistic effect”*

$L \rightarrow M$   $\sigma$ -bonding

$M \rightarrow L$   $\pi$ -bonding

**Metal to ligand  $\pi$ -donation ( $\pi$ -backbonding) lowers the energy of the HOMO making the metal less basic.  $\pi$ -backbonding stabilizes electron rich, low oxidation state metals. Very prevalent in late TM complexes.**

## MO description of the CO ligand

- In the CO molecule both the C and the O atoms are *sp hybridized*.
- The singly occupied  $sp$  and  $p_z$  orbitals on each atom form a  $\sigma$  and a  $\pi$  bond, respectively.

- This leaves the C  $p_y$  orbital empty, and the O  $p_y$  orbital doubly occupied, and so the second  $\pi$  bond is formed only after we have formed a **dative bond** by transfer of the lone pair of O  $p_y$  electrons into the empty C  $p_y$  orbital.

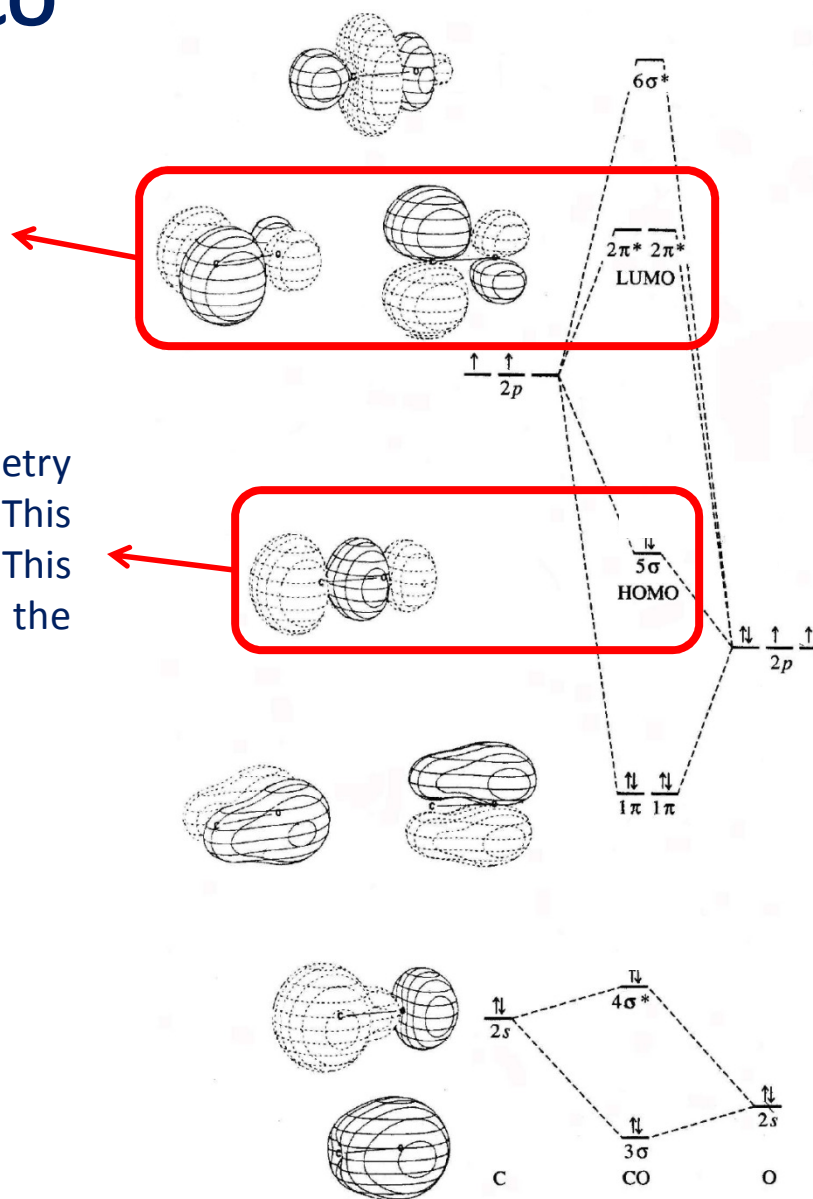

- This transfer leads to a  $\text{C}^{\delta-}-\text{O}^{\delta+}$  polarization of the molecule, which is almost exactly canceled out by a partial  $\text{C}^{\delta+}-\text{O}^{\delta-}$  polarization of all three bonding orbitals because of the higher electronegativity of oxygen.
- The free CO molecule therefore has a net dipole moment very close to zero.

# MO correlation diagram for CO

The CO LUMO orbitals are anti bonding of  $\pi^*$  symmetry. These are empty orbitals and accept electron density from the metal centre via  $\pi$ -backbonding with the metal  $t_{2g}$  orbitals.

The CO HOMO orbital is a bonding orbital of  $\sigma$  symmetry with significant electron density on the carbon. This orbital forms a  $\sigma$  bond with metal p and  $e_g$  orbitals. This is a filled orbital and donates electron density to the metal centre.

- The metal  $e_g$  orbital forms a  $\sigma$  bond with the HOMO orbital of CO.
- As shown on previous slides this HOMO is a  $\sigma$  orbital based on carbon.
- The metal  $t_{2g}$  orbitals form a  $\pi$  bond with the CO  $\pi^*$  LUMO (again polarized toward C)
- The metal HOMO, the filled M  $d\pi$  orbital, back donates to the CO LUMO increasing electron density at both C and O because CO  $\pi^*$  has both C and O character.
- The result is that C becomes more positive on coordination, and O becomes more negative. This translates into a polarization of the CO on binding.

- This metal-induced polarization chemically activates the CO ligand.
- It makes the carbon more sensitive to nucleophilic attack and the oxygen more sensitive to electrophilic attack.
- The polarization will be modulated by the effect of the other ligands on the metal and by the net charge on the complex.
- In  $\text{LnM}(\text{CO})$ , the CO carbon becomes particularly  $\delta^+$  in character if the L groups are good  $\pi$  acids or if the complex is cationic, e.g.  $\text{Mo}(\text{CO})_6$  or  $[\text{Mn}(\text{CO})_6]^+$ , because the CO-to-metal  $\sigma$ -donor electron transfer will be enhanced at the expense of the metal to CO back donation.
- If the L groups are good donors or the complex is anionic, e.g.  $\text{Cp}_2\text{W}(\text{CO})$  or  $[\text{W}(\text{CO})_5]^{2-}$ , back donation will be encouraged, the CO carbon will lose its pronounced  $\delta^+$  charge, but the CO oxygen will become significantly  $\delta^-$ .

- The range can be represented in valence bond terms the extreme in which CO acts as a pure  $\sigma$  donor, through to the extreme in which both the  $\pi_x^*$  and  $\pi_y^*$  are both fully engaged in back bonding.

CO stretching frequencies measured for Ni(CO)<sub>3</sub>L where L are PR<sub>3</sub> ligands of different  $\sigma$ -donor abilities. [ $\nu(\text{CO}) = 2143 \text{ cm}^{-1}$ ]

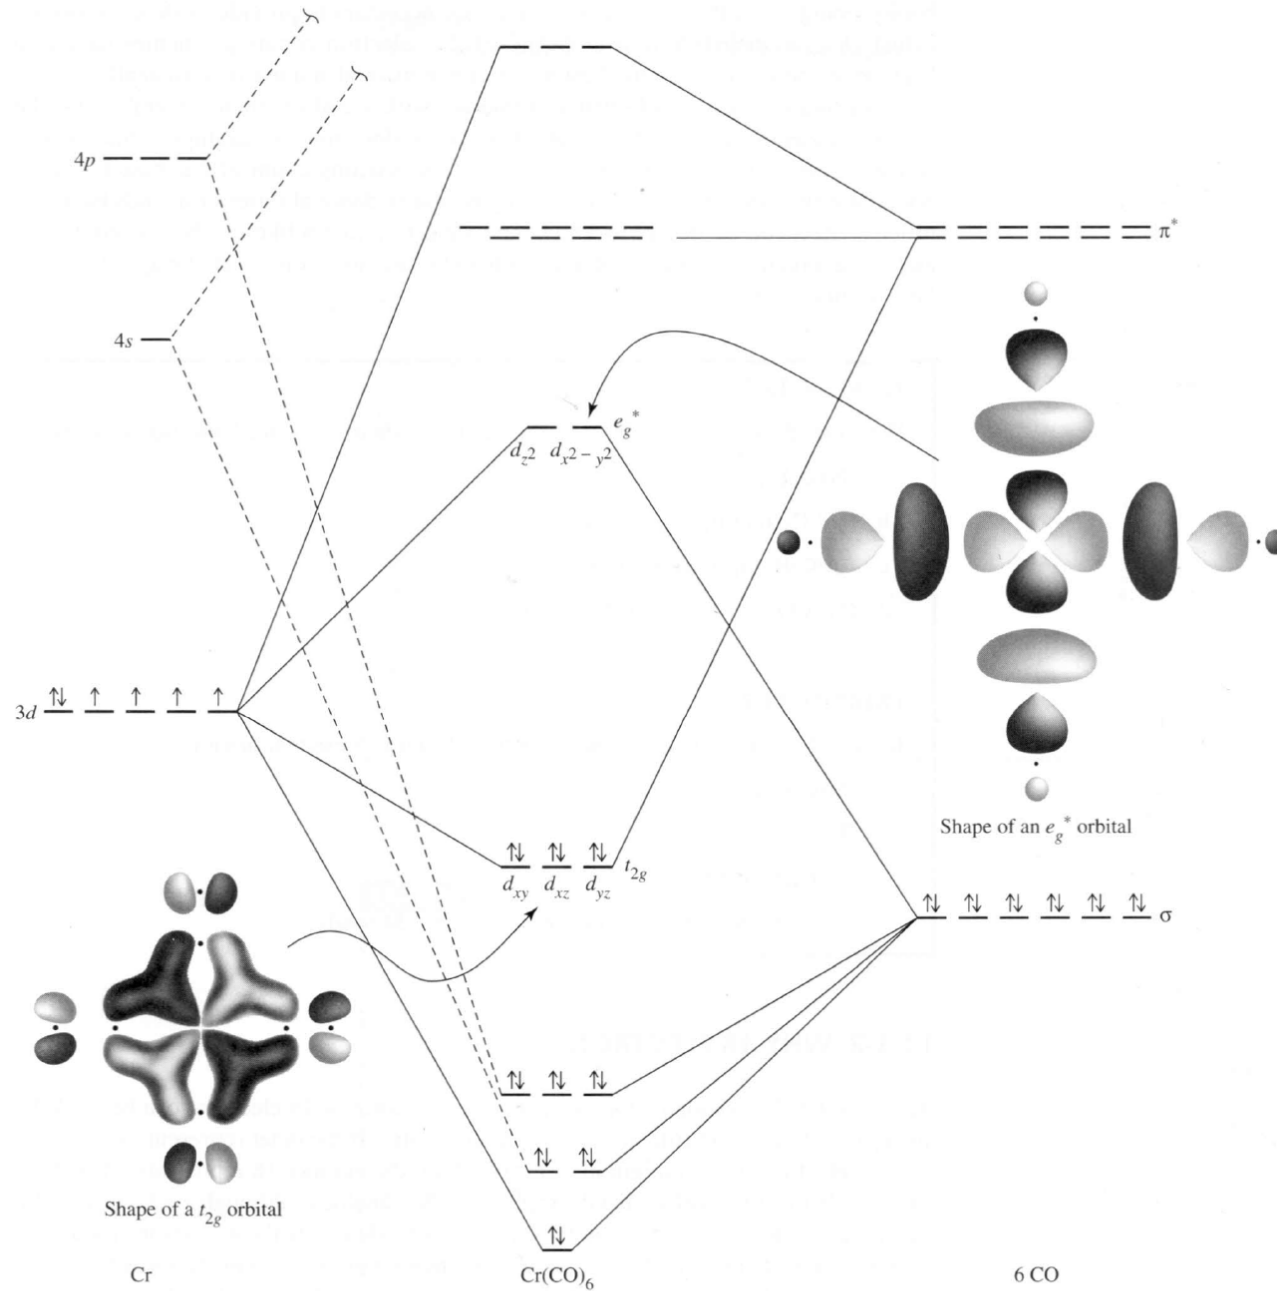

The increase in electron density at the nickel from PR<sub>3</sub>  $\sigma$ -donation is dispersed through the M-L  $\pi$  system *via*  $\pi$ -backbonding. Much of the electron density is passed onto the CO  $\pi^*$  and is reflected in decreased  $\nu(\text{CO})$  stretching frequencies which corresponds to weaker CO bonds.

$$\nu = \frac{1}{2\pi c} \left[ \frac{f}{(M_x M_y)/(M_x + M_y)} \right]^{1/2}$$

**Recall: Band position in IR is governed by :**

1. force constant of the bond ( $f$ ) and
2. individual masses of the atoms ( $M_x$  and  $M_y$ ).

Stronger bonds have larger force constants than weaker bonds.

**FIGURE 13-8** Molecular Orbital Energy Levels of  $\text{Cr}(\text{CO})_6$ . (Adapted with permission from G. O. Spessard and G. L. Miessler, *Organometallic Chemistry*, Prentice Hall, Upper Saddle River, NJ, 1997, pp. 53–54, Figs. 3-2 and 3-3.)

# $\pi$ -acceptor effects on reactivity

Semmelhack *JACS* 1980 (102) 5926

CO's render the electron rich Cr metal electrophilic via strong  $\pi$ -backbonding. Complexation of benzene with the electrophilic  $\text{Cr}(\text{CO})_3$  fragment withdraws electron density from the aromatic ring activating it towards nucleophilic attack.

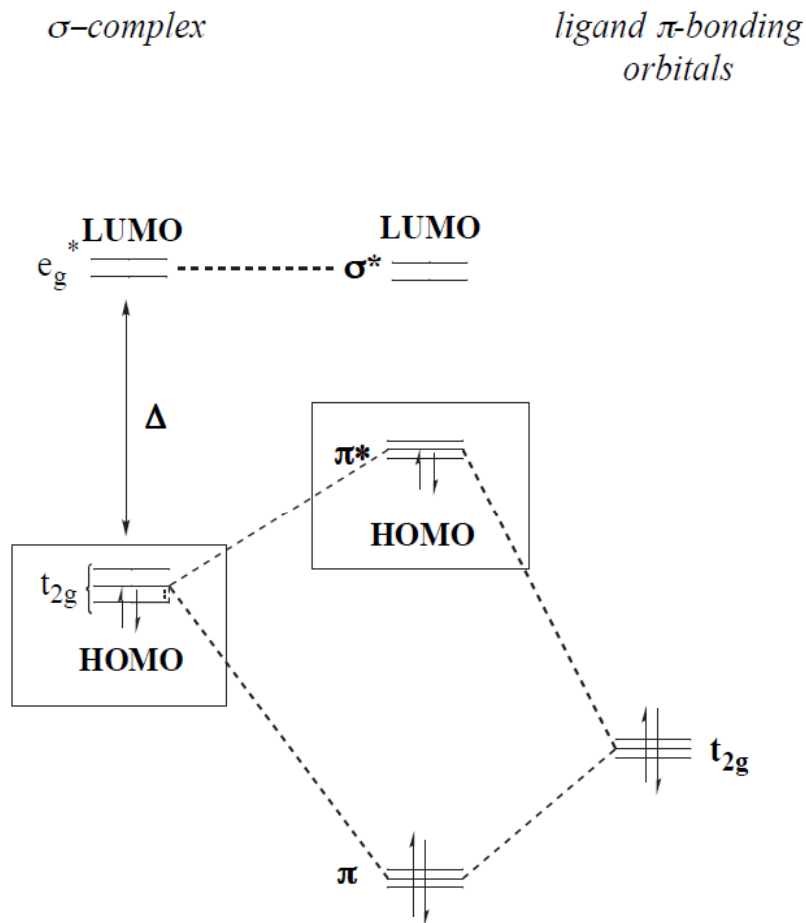

Acrolein is thought to act as a  $\pi$ -acid, withdrawing electron density from the Ni(II) complex via  $\pi$ -backbonding and promoting elimination of the diethyl fragment to reduce the metal.

## MO description for L→M $\pi$ -donor system in an $O_h$ complex

- In the L→M  $\pi$ -donor system filled p ligand orbitals exist slightly lower in energy than the metal  $t_{2g}$  set with which overlap occurs.
- The bonding  $t_{2g}$  MO's formed are again lower in energy than the initial metal  $t_{2g}$  set, however, the corresponding  $t_{2g}^*$  anti-bonding MO's are lower in energy than the  $e_g^*$   $\sigma$  anti-bonding orbitals.
- Additionally, as the ligand  $t_{2g}$  p orbitals are initially filled and of lower energy than the metal  $t_{2g}$  set, the bonding  $t_{2g}$  MO's formed are filled by the ligand electrons, with the metal d electrons occupying the corresponding  $t_{2g}^*$  anti-bonding MO's .
- Thus the LFSE  $\Delta_o$  is decreased. The  $t_{2g}$  bonding MO's are stabilized which is countered by occupation of the  $t_{2g}^*$  anti-bonding orbitals.
- Overall this combined  $\sigma$  and p donation from ligand to metal results in an increased M-L bond order and a stronger bond, however, the metal now becomes more electron rich which can decrease the bond strengths of the remaining ligand set making ligand-metal  $\pi$  bonding a less favorable interaction.

# MO description for L → M π-donor system in an O<sub>h</sub> complex

L → M  $\sigma$ -bonding

L → M  $\pi$ -bonding

The energy of the HOMO is directly affected by M-L  $\pi$ -bonding. Ligand to metal  $\pi$ -donation increases the energy of the HOMO making the metal more basic.  $\pi$ -donor ligands stabilize electron poor, high oxidation state metals. Very prevalent for early TM complexes (low d electron count) and less so for late TM (high d electron count).

# Summary of $\pi$ -bonding in a $O_h$ complexes

$\pi$  donor ligands result in  $L \rightarrow M$   $\pi$  bonding, a smaller  $\Delta_o$  favoring high spin configurations and a decreased stability.

$\pi$  acceptor ligands result in  $M \rightarrow L$   $\pi$  bonding, a larger  $\Delta_o$  favoring low spin configurations with an increased stability.

# MO description of $\sigma$ only bonding in a square planar $D_{4h}$ transition metal complex

- Square planar complexes are of  $D_{4h}$  symmetry, i.e. of lower symmetry than  $O_h$ .
- The reducible representations of ligand  $\sigma$  bonding orbitals results in the representations  $A_{1g}$ ,  $E_u$  and  $B_{1g}$
- Through symmetry considerations the metals orbitals have the representations  $A_{1g}$ ,  $E_g$ ,  $B_{1g}$  and  $B_{2g}$  for the d set and  $E_u$  and  $A_{2u}$  for the p set. The s orbital remains  $A_{1g}$ .
- Bonding and corresponding anti-bonding MO's are thus formed from matching the four metal  $a_{1g}$ ,  $e_u$ ,  $b_{1g}$  d orbitals and the two  $e_u$  metal p orbitals with the ligand set.
- The metal  $a_{1g}$  only has a minor contribution to ligand bonding ( $x^2 + y^2$  component).
- The  $e_g$  and  $b_{2g}$  metal d orbitals and the metal  $a_{2u}$  remain non-bonding.
- Eight electrons provided by the ligands fill the lowest three levels of MO's ( $a_{1g}$ ,  $e_u$  and  $b_{1g}$ )
- Metal d electrons result in an equivalent filling of the  $b_{2g}$  and  $e_g$  non-bonding MO's and if necessary the  $a_{1g}^*$  anti-bonding MO's.
- High spin ground states are generally not observed (even with a small  $\Delta$ ) as this geometry is mostly favored by complexes of  $d^0$  and  $d^8$  electronic configurations.

**FIGURE 10-15**  $D_{4h}$  Molecular Orbitals, Including  $\pi$  Orbitals. Interactions with metal  $d$  orbitals are indicated by solid lines, interactions with metal  $s$  and  $p$  orbitals by dashed lines, and nonbonding orbitals by dotted lines.

- The lowest energy set contains the bonding orbitals, as in the simpler  $\sigma$  only diagram.
- The next higher set consists of the eight  $\pi$  donor orbitals of the ligand.
- Their interaction with the metal orbitals is small and has the effect of decreasing the energy difference between the orbitals of the next higher set.
- The third set of MO's is primarily metal d orbitals, modified by interaction with the ligand orbitals.
- The  $b_{2g}$ ,  $e_g$  and  $a_{1g}$  orbitals are all low and have small differences in energy whereas the  $b_{1g}$  orbital has a much higher energy.
- Eight electrons from the ligands form the  $\sigma$  bonds and the next sixteen  $\pi$  electrons can either  $\pi$  bond or remain essentially non-bonding, and the remaining electrons from the metal occupy the third set.

# MO description of $\sigma$ only bonding in a $T_d$ transition metal complex

- The  $\sigma$  bonding orbitals for tetrahedral ( $T_d$ ) complexes are easily determined on the basis of symmetry.
- The reducible representation of ligand bonding orbitals includes  $A_1$  and  $T_2$  allowing for a total of four bonding MO's.
- The energy level picture for the  $T_d$  d orbitals is inverted wrt the  $O_h$  picture, also the LFSE is now called  $\Delta_t$  and is typically smaller than  $\Delta_o$ .

**$\sigma$  only**

Metal  $\Gamma = A_1 + E + T_2$

Ligand  $\Gamma = A_1 + T_2$

# MO description of $\sigma$ only bonding in a $T_d$ transition metal complex

The tetrahedral geometry is electronically favored by  $d^4$  or  $d^{10}$  metal complexes where the non-bonding orbitals are either 1/2 or entirely filled, respectively.

Symmetry adapted linear combinations (SALCs) of ligand bonding orbitals

## $\pi$ bonding in $T_d$ transition metal complexes

- The  $\pi$  bonding orbitals for tetrahedral ( $T_d$ ) complexes are more difficult to visualize.
- The reducible representation of  $\pi$  bonding ligand orbitals includes  $A_1$ ,  $T_1$ ,  $T_2$  and  $E$ .
- $T_1$  has no matching metal orbitals,  $E$  matches  $dz^2$  and  $dx^2-y^2$ , and  $T_2$  matches  $dxy$ ,  $dxz$ , and  $dyz$  metal orbitals.
- The  $E$  and  $T_2$  interactions lower the energy of the bonding orbitals, and raise the corresponding anti-bonding orbitals, for a net increase in  $\Delta_t$ .

**FIGURE 10-18** Molecular Orbitals for Tetrahedral Ni(CO)<sub>4</sub>. C. W. Bauschlicher, Jr., and P. S. Bagus, *J. Chem. Phys.*, **1984**, *81*, 5889, argue that there is almost no σ bonding from the 4s and 4p orbitals of Ni, and that the d<sup>10</sup> configuration is the best starting place for the calculations, as shown here. G. Cooper, K. H. Sze, and C. E. Brion, *J. Am. Chem. Soc.*, **1989**, *111*, 5051, include the metal 4s as a significant part of σ bonding, but with essentially the same net result in molecular orbitals.

- For Ni(CO)<sub>4</sub> the interactions of the CO  $\sigma$  and  $\pi$  ligand orbitals with the metal orbitals are probably small.
- Much of the bonding is from M $\rightarrow$ L p bonding.
- In cases in which the d orbitals are not fully occupied, s bonding is likely to be more important, with resulting shifts of the  $a_1$  and  $t_2$  orbitals to lower energy and the 4s and 4p orbitals to higher energies.
